Objectives of Topic

Understanding of:
- Basic wood behavior
- Typical framing methods
- Main types of lateral force resisting systems
- Expected response under lateral loads
- Sources of strength, ductility and energy dissipation
- Basic shear wall construction methods
- Shear wall component behavior
- Analysis methods
- Code requirements

Basic Wood Material Properties

Wood is orthotropic
- Varies with moisture content
- Main strength axis is longitudinal - parallel to grain
- Unique, independent, mechanical properties in 3 different directions
- Radial and tangential are "perpendicular" to the grain – substantially weaker

Basic Wood Material Properties

"Timber is as different from wood as concrete is from cement."
– Madsen, Structural Behaviour of Timber

Concept of "wood" as "clear wood": design properties used to be derived from clear wood with adjustments for a range of "strength reducing characteristics."
- Concept of "timber" as the useful engineering and construction material: "In-grade" testing (used now) determines engineering properties for a specific grade of timber based on full-scale tests of timber, a mixture of clear wood and strength reducing characteristics.

Basic Wood Material Properties

Sample DFL longitudinal design properties:
- Modulus of elasticity: 1,800,000 psi
- Tension (parallel to grain): 1,575 psi
- Bending: 2,100 psi
- Compression (parallel to grain): 1875 psi

Basic Wood Material Properties

Sample DFL perpendicular to grain design properties:
- Modulus of elasticity: 45,000 psi (2.5 ~ 5 % of E_l)
- Tension (perpendicular to grain): 180 to 350 psi
- Compression (perpendicular to grain): 625 psi.
- Failure stresses. Timber is extremely weak for this stress condition. It should be avoided if at all possible, and mechanically reinforced if not avoidable.
- Note that this is derived from a serviceability limit state of ~ 0.04" permanent deformation under stress in contact situations. This is the most "ductile" basic wood property.
Basic Wood Material Properties

- Wood will shrink with changes in moisture content.
- This is most pronounced in the radial and tangential directions (perpendicular to grain).
- May need to be addressed in the LFRS.

Wood Structure Construction Methods: Gravity

Post and Beam
- Space frame for gravity loads.
- Moment continuity at joint typically only if member is continuous through joint.
- Lateral resistance through vertical diaphragms or braced frames.
- Knee braces as seen here for lateral have no code design procedure for seismic.

Typical Light-Frame Foundation: Slab-On-Grade
- Sill bolts at pressure treated sill to foundation.
- Bearing wall supporting gravity loads.
- "Shovel" footing with minimal reinforcing.

Typical Light-Frame Foundation: Raised Floor
- Rim joist
- Bearing wall supporting gravity loads
- Supplemental blocking under shear wall boundary members
- Crawl space under "raised" floor
Typical Light-Frame Foundation: Post Tensioning

- Sill bolts at pressure treated sill to foundation
- PT Slab
- Variation in slab thickness, thickened edges, etc.

Wood Structure Construction Methods: Lateral

Horizontal elements of LFRS

- Edge nailing (interior nailing not shown)
- Plywood or OSB panels
- Offset panel joints (stagger)

- Most structures rely on some form of nailed wood structural panels to act as diaphragms for the horizontal elements of the LFRS (plywood or oriented strand board – OSB).
- Capacity of diaphragm varies with sheathing grade and thickness, nail type and size, framing member size and species, geometric layout of the sheathing (stagger), direction of load relative to the stagger, and whether or not there is blocking behind every joint to ensure shear continuity across panel edges.

Wood Structure Construction Methods: Lateral

- Shear capacities for vertical plywood/OSB diaphragms are also given in the codes, with similar variables impacting their strength.
- Heavy timber braced frames (1997 UBC) and singly or doubly diagonal sheathed walls are also allowed, but rare.

Vertical element: nailed wood structural panel diaphragm
If a structure does not meet the code requirements for "prescriptive" or "conventional" construction, it must be "engineered."

As in other engineered structures, wood structures are only limited by the application of good design practices applied through principles of mechanics (and story height limitations in the code).

A dedicated system of horizontal and vertical elements, along with complete connectivity, must be designed and detailed.

### Diaphragm Terminology
- **Continuous Panel Edge**
  - Parallel to Load
  - Supported Edge
  - Continuous Panel Edge
  - Parallel to Load
  - Direction of load on diaphragm
  - Unblocked Edge
  - Diaphragm Sheathing

### Partial reprint of engineered wood structural panel diaphragm info in 2003 IBC Table 2306.3.1.
- Major divisions: Structural 1 vs. Rated Sheathing and Blocked vs. Unblocked panel edges.

### Shear Wall Design Tables
- Tables are for DFL or SYP – need to adjust values if framing with wood species with lower specific gravities.
- Partial reprint of engineered wood structural panel diaphragm info in 2003 IBC Table 2306.4.1.
- Tables are for DFL or SYP – need to adjust values if framing with wood species with lower specific gravities.
- NO UNBLOCKED edges allowed.

### Complete Load Path
- Earthquakes move the foundations of a structure.
- If the structure doesn't keep up with the movements of the foundations, failure will occur.
- Keeping a structure on its foundations requires a complete load path from the foundation to all mass in a structure.
- Load path issues in wood structures can be complex.
- For practical engineering, the load path is somewhat simplified for a "good enough for design" philosophy.
Wood Structure LFRS Design Methods: Engineered

Complete Load Path

- Diaphragm to shear wall
- Overturning tension/compression to foundation
- Overturning tension/compression through floor
- Shear transfer through floor
- Shear transfer to foundation
Traditionally, many simple wood structures have been designed without "engineering.

Over time, rules of how to build have been developed, most recently in the 2003 International Residential Code (IRC).

For the lateral system, the "dedicated" vertical element is referred to as a braced wall panel, which is part of a braced wall line.

Based on SDC and number of stories, rules dictate the permissible spacing between braced wall lines, and the spacing of braced wall panels within braced wall lines.

While rules exist for the "dedicated" elements, testing and subsequent analysis has show these structures do not "calc out" based on just the strength of braced wall panels.

In reality, the strength, stiffness, and energy dissipation afforded by the "nonstructural" elements (interior and exterior sheathing) equal or exceed the braced wall panels in their contribution to achieving "life safety" performance in these structures.

Load path not explicitly detailed.

Example 2003 IRC Spacing Requirements for Braced Wall Lines

Example of Braced Wall Panel construction (2003 IRC references)

Perimeter nails at 6" o.c. (per Table R602.3-1)

All vertical panel joints shall occur over studs (per R602.10.7)

All horizontal panel joints shall occur over a minimum of 1 ½" blocking (per R602.10.7)

Prescriptive provisions in the 2003 IRC are more liberal than in the 2003 NEHRP Provisions.

The NEHRP Provisions and Commentary can be downloaded from http://www.bssconline.org. Also available from FEMA and at the BSSC website is FEMA 232, an up to date version of the Homebuilders’ Guide to Earthquake-Resistant Design and Construction.

Unlike seismic design loads, wind design loads are representative of the real expected magnitude.

When built properly, structural damage should be low.

Missile or wind born projectile damage can increase damage (this could potentially breach openings and create internal pressures not part of the design).
Expected Response Under Lateral Load: Seismic

- Engineered wood structures are thought of as having good flexibility/ductility, but can also be quite brittle.
- Wood structures can be engineered with either "ductile" nailed wood structural panel shear walls or "brittle" gypsum board and/or stucco shear walls as their primary LFRS.
- 2003 IBC R factors: Wood – 6.5; All Others – 2.0.

Sources of Strength for Seismic Lateral Resistance

- Rough estimates for engineered single family home
  - Gypsum board interior sheathing and stucco exterior sheathing: 50%
  - Nailed wood structural panel shear walls: 50%

Sources of Strength for Seismic Lateral Resistance

- Rough estimates for prescriptive single family home
  - Gypsum board interior sheathing and stucco exterior sheathing: 70%
  - Braced Wall Panels: 30%

Sources of Strength for Seismic Lateral Resistance

- Rough estimates for engineered light commercial structures
  - Gypsum board interior sheathing and stucco exterior sheathing: 30%
  - Nailed wood structural panel shear walls: 70%

Sources of Ductility and Energy Dissipation in Wood Structures

- Stress in the wood
  - Tension parallel to the grain: not ductile, low energy dissipation

Sources of Ductility and Energy Dissipation in Wood Structures

- Stress in the wood
  - Tension perpendicular to the grain: not ductile, low energy dissipation

- Need to have positive wall ties to perpendicular framing
Sources of Ductility and Energy Dissipation in Wood Structures

Positive Wall Tie

Stress in the wood
- Compression perpendicular to the grain: ductile, but not recoverable during and event – one way crushing similar to tension only braced frame behavior – ductile, but low energy dissipation
- Design allowable stress should produce ~0.04” permanent crushing

Stress in the fastener
- Nailed joint between sheathing and framing is source of majority of ductility and energy dissipation for nailed wood structural panel shear walls.
- The energy dissipation is a combination of yielding in the shank of the nail, and crushing in the wood fibers surrounding the nail.
- Since wood crushing is nonrecoverable, this leads to a partial “pinching” effect in the hysteretic behavior of the joint.
- The pinching isn’t 100% because of the strength of the nail shank undergoing reversed ductile bending yielding in the wood.
- As the joint cycles, joint resistance climbs above the pinching threshold when the nail “bottoms out” against the end of the previously crushed slot forming in the wood post.

Individual nail test

Full-scale shear wall test

Sources of Ductility and Energy Dissipation in Wood Structures

Vertical Elements of the LFRS: Prescriptive

NEHRP Section 12.4
- Numerous geometry limitations
- Two types of braced wall panel construction: gypsum wall board and wood structural panel

IRC 2003 Methods
- Numerous geometry limitations
- Numerous types of braced wall panel construction: NEHRP methods + ~10 more
Vertical Elements of the LFRS: Engineered

**NEHRP Methods**
- Nailed/stapled wood structural panel
- Cold-formed steel with flat strap tension-only bracing
- Cold-formed steel with wood structural panel screwed to framing

**IBC 2003 Methods**
- Nailed wood structural panel shear walls
- Sheet steel shear walls
- Ordinary steel braced frames
- All others: gypsum and stucco
- Proprietary shear walls

Wall Performance Based on Testing

- First cyclic protocol to be adopted in the US for cyclic testing of wood shear walls.
- 62 post yield cycles.
- Found to demand too much energy dissipation compared with actual seismic demand.
- Can result in significant underestimation of peak capacity and displacement at peak capacity.

Code Basis of Design Values

Nailed Wood Structural Panel Shear Walls
- Values currently in the code were developed by the APA – The Engineered Wood Association (used to be the American Plywood Association) in the 1950s.
- These values are based on a principles of mechanics approach.
- Some monotonic testing was run to validate procedure.
- Testing was conducted on 8'x8' walls (1:1 aspect ratio), with very rigid overturning restraint.
- Test was more of a sheathing test, not shear wall system test.
- Extrapolation of use down to 4:1 aspect ratio panels proved problematic on 1994 Northridge earthquake.
- Code now contains provisions to reduce the design strength of walls with aspect ratios (AR's) > 2:1 by multiplying the base strength by a factor of 2 / AR.

Proprietary Wood Structural Panel Shear Walls:
- Proprietary shear wall systems for light frame construction have been developed to provide higher useable strength when the AR exceeds 2:1.
- Values are determined according to Acceptance Criteria 130 (AC130) developed by the International Code Council Evaluation Services (ICC ES).
- AC130 requires full-scale cyclic testing of the wall seeking approval based on either SPD or CUREE protocols.
- Design rating based on either strength (ultimate / safety factor) or displacement (deflection which satisfies code deflection limits based on C_d, the deflection amplification factor associated with the rated R factor, and the appropriate maximum allowed inelastic drift ratio).

Typical Woodframe Analysis Methods

- Flexible diaphragm analysis
- Rigid diaphragm analysis

Cyclic Test Protocols -- CUREE

Cyclic Test Protocols TCCMAR (SPD)

**Worry about it??**
Typical Woodframe Analysis Methods

Flexible Diaphragm Analysis

- Lateral loads distributed as if diaphragm is a simple span beam between lines of lateral resistance.
- Diaphragm loads are distributed to lines of shear resistance based on tributary area between lines of shear resistance.
- Worry about it??
  - No

Rigid Diaphragm Analysis

- Lateral loads distributed as if diaphragm is rigid, rotating around the CR.
- Force in shear walls is a combination of translational and rotational shear.
- Worry about it??
  - Yes

Typical Woodframe Analysis Methods

Comments on Analysis Methods

- Neither the rigid nor flexible diaphragm methods really represent the distribution of lateral resistance in a typical structure.
- Both methods (typically) ignore the stiffness distribution of interior and exterior wall finishes.
- Wood structural diaphragms are neither “flexible” or “rigid” – they are somewhere in between. “Glued and screwed” floor sheathing makes floors more rigid than flexible. The nailing of interior wall sill plates across sheathing joints has the same effect. Exterior walls can act as “flanges”, further stiffening the diaphragm.
- However, encouraging rigid diaphragm analysis is also encouraging the design of structures with torsional response – may not be a good thing!

Rigid Diaphragms: When are they Rigid?

- 2003 NEHRP Recommended Provisions in Sec. 12.1.2.1 refers to the ASD/LRFD Supplement, Special Design Provisions for Wind and Seismic, American Forest and Paper Association, 2001:
  “A diaphragm is rigid for the purposes of distribution of story shear and torsional moment when the computed maximum in-plane deflection of the diaphragm itself under lateral load is less than or equal to two times the average deflection of adjoining vertical elements of the lateral force-resisting system of the associated story under equivalent tributary lateral load.” (Section 2.2, Terminology)
- Same definition in 2003 IBC Sec. 1602.

Rigid Diaphragms: When Are They Rigid?

- FEA: nail-level modeling is possible, with good correlation to full-scale testing.
- Requires a "true direction" nonlinear spring for the nails, as opposed to paired orthogonal springs.

Advanced Analysis

- Comparison of Test and Analysis Results

![Graph of Top of Wall Deflection vs. Applied Load at Top of Wall (Kips)]
Advanced Analysis

- NLTHA: rules based phenomenological elements fitted to full scale test data to predict structural response.
- Good correlation to simple tests – more work needed for complex, full structures.

Summary

- Timber structures have a good track record of performance in major earthquakes.
- Their low mass and good damping characteristics help achieve this.
- The orthotropic nature of wood, combined with the discontinuous methods of framing wood structures, requires careful attention to properly detailing the load path.
- There is still much room for improvement in our understanding of force distribution within wood structures, and the development of design tools to better model this.
