GROUND MOTION PREDICTION EQUATIONS FOR EASTERN NORTH AMERICA USING THE HYBRID EMPIRICAL METHOD

S. Pezeshk, A. Zandieh, K. Campbell, B. Tavakoli

Hybrid Empirical Method

- The hybrid empirical method (Campbell, 1981-2011) is a procedure to develop GMPEs in areas with sparse ground motions.
- In the hybrid empirical method, the target region (ENA in this study) ground motions are predicted from the host region (WNA in this study) empirical GMPEs using modification factors between two regions.
- These theoretical modification factors are calculated as the ratio of stochastic simulations of ground motions for two regions.
- Using regional seismological parameters in simulations, the adjustment factors reflect the regional differences in source, path, and site.
- In the hybrid empirical method, the empirically derived ground-motion models for the host region are mapped onto the target region considering the differences in regional seismological properties.
Hybrid Empirical Method

Hybrid Empirical Method:

\[ Y_{\text{ENA estimated}} = Y_{\text{WNA empirical}} \times \frac{Y_{\text{ENA stochastic}}}{Y_{\text{WNA stochastic}}} \]

The hybrid empirical method is used by many authors to develop GMPE in ENA (Campbell 2003, 2007, 2011, 2014; Tavakoli and Pezeshk 2005; Pezeshk, Zandieh, and Tavakoli 2011)

Adjustment Factor
(Accounts for earthquake source, wave propagation, and site-response differences between the two regions)

The purpose of this study is to update the Pezeshk, Zandieh, and Tavakoli (2011) and Campbell (2007, 2011) models to derive a new hybrid empirical GMPE for ENA using five new ground-motion prediction models developed by the PEER center (NGA-West2).

Furthermore, recent new information on ENA seismological parameters such as the stress parameter, geometric spreading, anelastic attenuation, and the site response term are used to update the GMPE.
Stochastic Simulations

- Point-source stochastic simulation of ground motion amplitudes for both WNA and ENA are determined.

Seismological Parameters for WNA

- Response spectra for WNA earthquakes for $M<6$ can be well described by a simple point-source stochastic model.
- We are finding the best fit for seismological parameters by matching stochastic simulation to the mean GMPEs of NGA-West2 for range of magnitudes and distances.
- We perform a set of inversion to obtain the best and consistent set of parameters by matching stochastic simulations with mean GMPEs for magnitudes from 3.5 to 6.

GMPEs

- ASK14: Abrahamson & Silva & Kamai 2014 NGA West-2 Model
- BSSA14: Boore & Stewart & Seyhan & Atkinson 2014 NGA West-2 Model
- CB14: Campbell & Bozorgnia 2014 NGA West-2 Model
- CY14: Chiou & Youngs 2014 NGA West-2 Model
- I14: Idriss 2014 NGA West-2 Model

**Figure:**

- **M=7, Distance 30 km**
  - PSA (g) vs. Period (s)
  - Geometric Mean

**Graph Details:**
- PSA values range from 0.01 to 0.3 g.
- Period ranges from 0.01 to 10 seconds.
- Different GMPEs are represented by distinct colors and line styles.
BSSA-14 - NGA West 2 Parameters

- $V_s30 = 760$ m/s
- Region = 0 (California)
- Basin Depth $Z_{2.5}$ and $Z1 = 999$ (use default values)
- $R_{jb}$ is converted to $R_{rup}$ using Scherbaum et al. (2004) distance conversion for generic style of faulting.

Effective Distance

To mimic the finite-fault effects in point-source simulations, the effective distance, $R'_{rup}$, of Atkinson and Silva (2000) and Yenier and Atkinson (2014) recommendations are used in our stochastic simulations.

$$R'_{rup} = \sqrt{R^2_{rup} + h^2}$$

$$\log h = \max(-0.05 + 0.15M, -1.72 + 0.43M)$$
Geometric Spreading Vs. Rupture Distance

$$\log h = \max(-0.05 + 0.15M, -1.72 + 0.43M)$$

$$R_{rup}' = \sqrt{R_{rup}^2 + h^2}$$

Seismological Parameters for WNA

- Path Duration
  - We adopted Boore and Thompson (2014) path duration.
  - We followed Yenier and Atkinson (2014) to convert Boore and Thompson (2014) nodal rupture distances using the effective distances:

<table>
<thead>
<tr>
<th>Distance (km)</th>
<th>Path Duration (s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.32</td>
</tr>
<tr>
<td>6.5</td>
<td>2.32</td>
</tr>
<tr>
<td>44.7</td>
<td>8.32</td>
</tr>
<tr>
<td>124.8</td>
<td>10.9</td>
</tr>
<tr>
<td>175</td>
<td>17.5</td>
</tr>
<tr>
<td>269</td>
<td>34.1</td>
</tr>
</tbody>
</table>

Path duration increases with distance at a rate of 0.156s/km after the last nodal point.
Stress Parameter for WNA

- For our inversion for WNA, we use the Brune single-corner frequency model.

- The stress parameter controls the spectral shape at high frequencies along with the site parameter $\kappa_0$.

- Yenier and Atkinson (2014) proposed an average stress parameter based on spectral shape of 100 bars for events of $M \geq 5$ with a significant constant that multiplies predicted source amplitudes. They proposed:

$$\log \Delta \sigma = \min(1.176 + 0.412(M - 3.0), 2)$$

$$= \begin{cases} 
15 & M = 3 \\
39 & M = 4 \\
100 & M \geq 5 
\end{cases}$$

- We determine the mean value of the stress parameter to be 125 based on our inversion.

$\kappa_0$ Parameter for WNA

- $\kappa_0$ based on the inversion is determined to be 0.0375.

- This is consistent with Linda Al Atik recent work.

Table 9.3.2-1: Host kappa estimates for CY14 estimated using the UVT approach for the 3 f1f2 definitions for scenarios M=5.5, 6.5, 7.5 and $R_s$ of 5, 10, and 20 km.
Bilinear Geometric Spreading for WNA

- We considered a bilinear geometric spreading:

\[
Z(R) = \begin{cases} 
R^{b_1} & R \leq R_1 \\
R_1^{b_1-b_2} R^{b_2} & R > R_1 
\end{cases}
\]

- We determine the mean value of \(b_1\) and \(R_1\) based on our inversion to be.

\[
b_1 = -1.0374 \\
R_1 = 96 \text{ km}
\]

Anelastic Attenuation, \(Q(f)\) for WNA

- The anelastic attenuation, \(Q(f)\) controls the decay of ground motion amplitude at large distances (especially, at low periods or high frequencies).

\[
Q(f) = 243 f^{-0.446}
\]
Residuals

M = 3.5

M = 4

M = 5

M = 6

f = 0.5 Hz

f = 1.0 Hz

f = 5 Hz

Seismological Parameters for ENA

- The stress parameter of 400 is used in our point source stochastic simulations:
  - Consistent with Boore and Thompson (2014) path duration

Stress-drop

- Use of MMI data
  - Shows a large difference between CENA and WUS
  - Implies about a factor of 3 increase in stress drops from WUS
Seismological Parameters for ENA

Boore and Thompson (2014)

We determined the mean values of $b_1$, $b_2$, $R_1$, and $R_2$ based on our inversion to be:

$$b_1 = -1.0387, b_2 = -0.83$$

$$R_1 = 45 \text{ km}, R_2 = 125 \text{ km}$$

We considered a Trilinear geometric spreading:

$$Z(R) = \begin{cases} 
R^2 & R \leq R_1 \\
R^2 \left( \frac{R}{R_1} \right)^{b_1} & R_1 < R \leq R_2 \\
R^2 \left( \frac{R}{R_1} \right)^{b_1} \left( \frac{R}{R_2} \right)^{b_2} & R > R_2 
\end{cases}$$
Trilinear Geometric Spreading for ENA

We determine the mean values of $b_1$, $b_2$, $R_1$, and $R_2$ based on our inversion to be:

$$Z(R) = \begin{cases} R^{b_1} & R \leq R_1 \\ R^{b_1} \left( \frac{R}{R_1} \right)^{b_2} & R_1 < R \leq R_2 \\ R^{b_1} \left( \frac{R}{R_2} \right)^{b_2} & R > R_2 \end{cases}$$

$$b_1 = -1.3, b_2 = 0$$

$$R_1 = 60 \text{ km}, R_2 = 120 \text{ km}$$

Q and Geometric Spreading for ENA

$$Q(f) = 440 f^{0.47}$$

- Consider all locations except Gulf
- Made corrections for site
Correction for Site Effects (BSSA2014)

\[ F_{s,\beta} = \ln(F_{ln}) + \ln(F_{nl}) \]

\[
\ln(F_{ln}) = \begin{cases} 
  c \ln \left( \frac{V_{S30}}{V_{ref}} \right) & V_{S30} \leq V_c \\
  c \ln \left( \frac{V_{S30}}{V_{ref}} \right) & V_{S30} > V_c 
\end{cases}
\]

where \( c \) describes the \( V_{S30} \) scaling in the model, \( V_c \) is the limiting velocity beyond which ground motions no longer scale with \( V_{S30} \), and \( V_{ref} \) is the site condition for which the amplification is unity (taken as 760 m/sec).

\[
\ln(F_{nl}) = f_1 + f_2 \ln \left( \frac{PGA_r + f_3}{f_3} \right)
\]

\( PGA_r \) is the median peak horizontal acceleration for reference rock (taken as \( V_{S30} = 760 \) m/sec).
HYBRID EMPIRICAL GROUND-MOTION PREDICTION EQUATIONS
FOR EASTERN NORTH AMERICA

\[
\log(\bar{Y}) = c_1 + c_2 M_w + c_3 M_w^2 + (c_4 + c_5 M_w) \times \min\{\log(R) , \log(R_i)\} + \\
(c_6 + c_7 M_w) \times \max\{\min\{\log(R / R_i), \log(R / R_i), 0\}, 0\} \\
+ (c_8 + c_9 M_w) \times \max\{\log(R / R_i), 0\} + c_{10} R
\]

where

\[
R = \sqrt{R_{top}^2 + c_{11}^2}
\]

The mean aleatory standard deviation of to be associated with the predictions is defined as a function of earthquake magnitude:

\[
\sigma_{\log(\bar{Y})} = \begin{cases} 
  c_{12} M_w + c_{13}, & M \leq 7 \\
  -6.95 \times 10^{-3} M_w + c_{14}, & M > 7
\end{cases}
\]

Hybrid Empirical GMPEs for ENA using Hybrid Broadband Synthetic

A. Shahjouei and S. Pezeshk
Summary of the Procedure

- We used HEM GMPEs for ENA using a HBB simulation technique.
- HF synthetics using stochastic method are generated and combined with LF synthetics produced from kinematic source model and deterministic wave propagation.
- The most recent proposed seismological and geological parameters in the literature is implemented.
- Variability of some parameters are implemented in the generation approach.
- New GMPEs are based on synthetics generated:
  - Mag: M5.0 to M8.0 with increment of 0.5
  - Distance: Closest distance to the fault (Rjb) in distance range of 2–1000 km.
  - Reference rock velocity of 3000 m/s (HR)
- The results are compared with the other GMPEs and NGA-East database.

The Applied Procedure for Hybrid Broadband Synthetic

Hybrid Broadband (HBB) Synthetic Generation using Finite-Fault Modeling

- LF Green’s functions (DWFE method ~ COMPSYN)
- Slipp distribution
- Kinematic fault modeling
- Stress distribution
- HF Green’s functions (Stochastic method ~ SMSIM)
- Low freq. synth. (Sum over fault plane)
- Synchronize
- Combine
- Matched filter
- Hybrid broadband synthetic
- Max directional response (GMROT)
  - (Stochastic method)
Samples for Kinematic Earthquake Source Models for CENA
